

Hamlet on the Fly

7 February 2018

 <p>Hamlet on the Fly: To be or not to be a Foreleg?</p> <p>Lewis Held Wed., February 7, 2018 4 PM, Biology Room 101</p>	<p>One reason I chose the Hamlet theme:</p> <p>There will be lots of plot twists in the story.</p>
<p>Q: How do cells decide what to be? A: They make a series of binary choices with "master" (Hox) genes in control.</p>  <p>Internal nodes Hox = CEO Terminal nodes anatomy From Rabold et al. (2015)</p>	<p>Humans have ~200 diff. cell types: skin, nerve, muscle, etc. Q: How do cells adopt correct identities during dev't? A: ~BINARY (be/not be) decisions. Genes = ON/OFF. By the end of talk: show that this view is partly incorrect.</p>
	<p>Glorious diversity of animals on Earth.</p> <p>We normally think about animals as ADULTS.</p> <p>But every animal starts as a fertilized EGG.</p>
	<p>That includes you. = Your earliest selfie!</p> <p>Fertilized egg of a human is so tiny that it can fit on the head of a pin.</p>
	<p>Can't do expts on humans, so use other animals instead. Flies = useful.</p> <p>Fly dev't is interesting b/c the baby looks nothing like adult. Larva = maggot. Analogous to tadpole. Metamorphosis.</p>
	<p>Adult (imago) body is assembled like a quilt (jigsaw puzzle) from individual pieces.</p>
 <p>adult larva</p> <p>Discs: 1. Head 2. Cervical 3. Thoracic 4. Humeral 5. Eye-antennal 6. 1st Leg 7. 2nd Leg 8. 3rd Leg 9. Wing 10. Malpighia</p>	<p>Pieces = imaginal discs (\approx modules).</p> <p>They grow inside larva (\approx balloons) & evert.</p> <p>10 different identities.</p>
 <p>adult embryo</p>	<p>Discs (black ovals) come from diff. segments in the embryo. 6 head segments, 3 thoracic segments, & 10 abd. segments.</p>

	<p>Segmental identity is handled by Hox genes (clusters). Transcription factors w/ DNA-binding domain (homeobox).</p> <p>Same area codes in humans & flies (common ancestor). Humans have genes that are homologs of Scr & Ubx.</p>
<p>segmental identity</p> 	<p>Today: Focus on the 3 thoracic segments.</p> <p>Identities of T1 and T3 controlled by Hox genes Scr & Ubx.</p>
<p>bithorax mutant</p> 	<p>Many of you know the story of the “bi-thorax” mutation.</p> <p>Disable Ubx: T3 → T2.</p> <p>Haltere → wing.</p>
	<p>Hindleg also transforms → midleg. Foreleg & hindleg differ from midleg. Transverse rows = brushes to clean the eyes & wings. Also foreleg has sex comb = grasps female during mating.</p>
	<p>If you disable Scr, T1 leg → T2 identity.</p> <p>T-rows & sex comb disappear.</p> <p>Defaults to T2 state just like Ubx-LOF.</p>
<p>GOF experiment</p> 	<p>What happens if you force Scr to be expressed in all legs? Interesting b/c it confuses the cells → Reveal secrets? But backfired: confused me!</p> <p>GOF (Gain of Function). T1: no change expected. Q: T2 & T3 → T1 identity?</p>
	<p>Method: Gal4 & UAS transgenes.</p> <p>Distal-less driver (master) with Scr “slave”.</p> <p>UAS = Upstream Activating Sequence.</p>
	<p>Additional details of the approach we used. Gal80ts control timing via 18° vs. 29° C.</p> <p>Scabrous driver forces Scr to be expressed in bristle cells (& surrounding cells) only.</p>

	<p>Mug shots of hindleg basitarsus. T-rows on ANT = expected. But surprise: t-rows remain on POS! Confusing: Scr doesn't overrule Ubx?</p>
	<p>Midleg basitarsus: t-rows on both faces. Confusing: Scr normally only affects ANT. But evidently it can work on both POS & ANT.</p>
	<p>We had assumed that Scr → foreleg identity. RETHINK: Maybe its role is to induce t-rows? And it just so happens to only be expressed in ANT.</p>
	<p>No! Scr-GOF hardly affects POS of foreleg at all! Why not? Maybe engrailed is suppressing Scr? (Is that why Scr is normally confined to the ANT?)</p>
	<p>Although Scr is strongly expressed in t-rows & sex comb. I had assumed Scr is activated only on the ANT side. [C = Scr expression (dots = nuclei); C' = GFP (all cells).]</p>
	<p>Mug shots of hindleg basitarsus. T-rows on both faces. Easy to explain if Ubx → t-rows (like Scr → t-rows). On a roll. But then ... hit brick wall.</p>
	<p>Why isn't engrailed inhibiting Scr on the midleg? We argue that it is doing so, but Ubx makes up for it. Ubx is expressed in T2??? Yes! At low levels.</p>
	<p>The reason Ubx is expressed in the POS half of T2? Initially, Scr, Ubx, etc. = expressed in "parasegments." Segmentation gene hierarchy.</p>
	<p>Parasegments = offset from segments by engrailed stripe. Enigma. But humans also have phase shift: somites vs. vertebrae.</p>

	<p>Parasegment 5 includes POS side of T2.</p> <p>Ubx fades from wing disc. (High level in t-rows on hindleg.)</p> <p>But retained at low level (light green) in POS of midleg.</p>
<p>... so when we force Scr to be expressed on both sides, en partly suppresses Scr, but there might be enough Scr left to interact with Ubx so as to make t-rows on P side.</p>	<p>RECAP: Scr = partly suppressed by en, but enough remains for it to cooperate with low-level Ubx to elicit t-rows.</p> <p>Low Scr + Low Ubx → Exceed threshold.</p> <p>If so, then Scr should interact synergistically with Ubx ... WHEREVER they overlap. So re-examine the hindleg.</p>
<p>Test: See whether there are excess t-rows on the P side on the hindleg.</p>	<p>On the hindleg, Scr overlaps with HIGH-level Ubx.</p>
	<p>Yes! Synergy! Normally POS = only 1 row of 8 bristles.</p> <p>This is an evol. conserved hard-wired trait (50 MY old).</p> <p>But notice that Scr-GOF elicits as many as 9 t-rows total!</p>
	<p>Summary of quantitative data:</p> <p>Number of t-row bristles increases from 8 to 47 (mean).</p> <p>Review: Effects of Scr-GOF on T1, T2, T3. A/P ratios!</p>
<p>Conclusions:</p> <p>1. En partly blocks Scr-GOF on POS of all legs.</p>	<p>1. Scr gets confined to ANT b/c En inhibits it.</p> <p>Test: en-LOF clones on P side of leg. <i>Done by Teresa.</i></p>
<p>Conclusions:</p> <p>1. En partly blocks Scr-GOF on POS of all legs.</p> <p>2. Ubx makes up for the decrease on T2 & T3.</p>	<p>2. Scr and Ubx interact synergistically.</p> <p>Test: Express both together.</p>
<p>Conclusions:</p> <p>1. En partly blocks Scr-GOF on POS of all legs.</p> <p>2. Ubx makes up for this decrease on T2 & T3.</p> <p>3. Scr → a slow messenger vs. an instantaneous.</p> <p>Hox genes get "down in the weeds".</p>	<p>3. Hox genes (at late stages) ≈ paintbrushes for touch-up?</p> <p>Test: Disable Scr at late stages (sca-GAL4).</p> <p>DIRECTLY affecting downstream decisions.</p> <p>Leaving penthouse suite @ Trump Tower → assembly line.</p>

	<p>Similar thing in vertebrates. Late role ≠ early role.</p> <p>Re-purposing of Hox genes for non-segment roles.</p> <p>Ex.: Recruiting of Hox genes for finger identity</p>
	<p>Mutate Hox13 (d cluster) → “bear claw” phenotype.</p> <p>Thumb transforms into an ordinary finger.</p>
<p>Conclusions:</p> <ol style="list-style-type: none"> En partly blocks Scr-GOF on POS of all legs. Ubx makes up for this decrease on T2 & T3. Scr = a direct micromanager vs. an executive. Scr acts as a knob (analog) vs. switch (digital) 	<p>4. Scr acts as a knob (analog) vs. switch (digital). Ubx also.</p> <p>Best example of dosage effect = tibia in 1st leg of Scr-GOF.</p> <p>Excess Scr causes additional t-rows (10 vs. 6) on foreleg.</p>
	<p>Given these dosage effects, title → Measure for Measure?</p>
	<p>Or ... given that we've demoted these exalted Hox genes to the level of functioning of ordinary transcription factors, Maybe the title of talk → Much Ado About Nothing</p>
	<p>Acknowledgements: 3 undergrad apprentices: Andrew Davis, Rachel Aybar, and Zack Fitzgerald.</p> <p>Teresa Orenic did the staining of discs for Scr expression.</p>
	<p>Enigmatic result. Scr-GOF.</p> <p>Deleted macro- but not microchaetes.</p>
	<p>Summary of LOF effects.</p> <p>Time course: disable Scr.</p>

<p style="text-align: center;">Relevance?</p>	
	<p>Pitx1-LOF ≈ Liebenberg Syndrome.</p>
	<p>Qs → Evo-devo (E & D). G = Genetics. Playground.</p>
	
	<p>Same signaling pathways! DEEP homology. Conserved TOOLKIT.</p>
	<p>Fly legs vs. human legs. Look diff., but same recipe! [Gerard Campbell]</p>
<p style="text-align: center;">Scabrous Driver</p>
