## Introduction to ID-logic

ID-logic and common sense

- Defaults

- Ontologies

- Actions

ID-logic as a computational tool

The relation to ASP and LP

Future work & Conclusion

## ID-logic

### What is ID-logic?

ID-logic is an extension of classical logic with a new primitive for representing inductive definitions

Some questions

- ▶ Why are we interested inductive definitions?
- ▶ Why do we want a new primitive for this?
- ▶ Why extend classical logic?

## (Inductive) Definitions in Mathematics

- ▶ “Ordinary” definitions

A square is defined as a rectangle with equal height and width.

- ▶ Monotone inductive definitions

The transitive closure  $TC(R)$  of a binary relation  $R$  is inductively defined by the following rules:

- ▶  $\forall x, y$ , if  $(x, y) \in R$ , then  $(x, y) \in TC(R)$ ;
- ▶  $\forall x, y$ , if  $\exists z, (x, y), (y, z) \in TC(R)$ , then  $(x, z) \in TC(R)$ .

## (Inductive) Definitions in Mathematics (2)

- ▶ Non-monotone inductive definitions over a well-founded order

We define the relation  $S \models \phi$  between structures  $S$  and formulas  $\phi$  by the following induction (over length of formulas):

- ▶  $S \models P(t_1, \dots, t_n)$  if  $(t_1^S, \dots, t_n^S) \in P^S$ ;
  - ▶  $S \models \phi \wedge \psi$  if  $S \models \phi$  and  $S \models \psi$ ;
  - ▶  $S \models \phi \vee \psi$  if  $S \models \phi$  or  $S \models \psi$ ;
  - ▶  $S \models \exists x \phi$  if there exists  $d \in \text{Dom}(S)$ ,  $S \models \phi[x/d]$
  - ▶  $S \models \neg \phi$  if  $S \not\models \phi$
- ▶ Iterated inductive definitions

## Inductive definitions

In mathematics

- ▶ Inductive definitions occur quite often
- ▶ Offer **constructive** characterization of certain concepts
- ▶ Useful and well-understood way for representing certain kind of knowledge

Two different kinds of mathematical knowledge

- ▶ Definitions: State what a concept is
  - ▶ **Inductive** definitions are important part of this
- ▶ Propositions, theorems, . . . : State properties of concepts

## Classical logic

As a language for representing mathematical knowledge?

- ▶ Is well-suited for representing theorems etc.
- ▶ But expressing definitions is harder
  - ▶  $\forall x \text{ Square}(x) \Leftrightarrow \text{Rectangle}(x) \wedge \text{Height}(x) = \text{Width}(x)$
  - ▶  $\forall x, y \text{ R}(x, y) \Rightarrow \text{TC}(x, y)$   
 $\forall x, y (\exists z \text{ TC}(x, z) \wedge \text{TC}(z, y)) \Rightarrow \text{TC}(x, y)$
  - ▶  $\forall P \left( \begin{array}{l} (\forall x, y \text{ R}(x, y) \Rightarrow P(x, y)) \wedge \\ (\forall x, y (\exists z P(x, z) \wedge P(z, y)) \Rightarrow P(x, y)) \end{array} \right) \Rightarrow \text{TC} \subseteq P$
  - ▶ For non-monotone definitions: Explicitly encode well-founded order

## New inductive definition primitive

Offers a **uniform** and **straightforward** way of representing all previously mentioned kinds of inductive definitions

### In mathematical text

The transitive closure  $TC(R)$  of a binary relation  $R$  is inductively defined by the following rules:

- ▶  $\forall x, y$ , if  $(x, y) \in R$ , then  $(x, y) \in TC(R)$ ;
- ▶  $\forall x, y$ , if  $\exists z, (x, z), (z, y) \in TC(R)$ , then  $(x, y) \in TC(R)$ .

### In ID-logic

$$\left\{ \begin{array}{l} \forall x, y \quad TC(x, y) \leftarrow R(x, y). \\ \forall x, y \quad TC(x, y) \leftarrow \exists z \quad TC(x, z) \wedge TC(z, y). \end{array} \right\}$$

## A definition in ID-logic

$$\left\{ \begin{array}{l} \forall x, y \ TC(x, y) \leftarrow R(x, y). \\ \forall x, y \ TC(x, y) \leftarrow \exists z \ TC(x, z) \wedge TC(z, y). \end{array} \right\}$$

- ▶ Definition is a set of **definitional rules** between  $\{\}$

$$\forall \mathbf{x} \ P(\mathbf{t}) \leftarrow \phi.$$

- ▶ Defines number of predicates
- ▶ Other predicates are **open**, i.e., supposed to be given

## Semantics of a monotone definition $\Delta$

Given an interpretation for the **open** predicates, the **defined** predicates should be interpreted by the **least fixpoint** of the **operator** that derives the heads of all ground instantiations of rules of  $\Delta$  whose bodies are satisfied.

- ▶ Fix domain  $D$  and pre-interpretation  $F$
- ▶ Let  $R$  be an interpretation in  $D$  of the **open** predicates of  $\Delta$
- ▶ Let  $T_{\Delta}^R$  be the operator on interpretations in  $D$  of the **defined** predicates of  $\Delta$ , that maps  $S$  to  $S'$ , with for each defined  $P/n$ 
  - ▶  $P^{S'} = \{\mathbf{d} \in D^n \mid \text{for which}$
  - ▶  $\text{there exists } \forall \mathbf{x} \ P(\mathbf{t}) \leftarrow \phi. \in \Delta \text{ and } \mathbf{d}_{\mathbf{x}} \in D^{|\mathbf{x}|} \text{ such that}$
  - ▶  $\mathbf{d} = \mathbf{t}^{F[\mathbf{x}/\mathbf{d}_{\mathbf{x}}]} \text{ and } (R \cup S)[\mathbf{x}/\mathbf{d}_{\mathbf{x}}] \models \phi\}$
- ▶ Given this interpretation  $R$  for the **open** predicates, the interpretation of the **defined** predicates should be  $\text{lfp}(T_{\Delta}^R)$

How to extend this to **non-monotone** definitions?

## Semantics of such a definition (2)

Well-founded model

- ▶ Generalizes the intuitions behind least fixpoint construction
- ▶ To also apply to non-monotone definitions

For the kind of definitions typically occurring in mathematics

- ▶ This semantics coincides with their “usual interpretation”

For more complicated definitions

- ▶ It also does something reasonable

## Formal semantics of a definition

$S \models \Delta$  iff

- ▶ Use  $S$  to interpret open predicates of  $\Delta$
- ▶ Construct  $wfm_{S|_{Open_\Delta}}(\Delta)$  of  $\Delta$  given  $S|_{Open_\Delta}$
- ▶  $wfm_{S|_{Open_\Delta}}(\Delta)$  is two-valued and equal to  $S|_{Def_\Delta}$

Note that, although the semantics uses WFS which can be three-valued, models of a definitions are two-valued

## Formal semantics: Example

$$\left\{ \begin{array}{l} \forall x, y \ TC(x, y) \leftarrow R(x, y). \\ \forall x, y \ TC(x, y) \leftarrow \exists z \ TC(x, z) \wedge TC(z, y). \end{array} \right\}$$

$$\left\{ \begin{array}{l} R(A, B), R(B, C), \\ TC(A, B), TC(B, C), TC(A, C) \end{array} \right\} \models \Delta_{TC}$$

- ▶ If we interpret  $R/2$  by  $\{R(A, B), R(B, C)\}$
- ▶ The wfm of  $\Delta_{TC}$  is  $(\{TC(A, B), TC(B, C), TC(A, C)\}, \{TC(A, B), TC(B, C), TC(A, C)\})$

## ID-logic in full

**Syntax** is inductively defined as:

- ▶ A definition  $\Delta$  is a formula
- ▶ An atom  $P(\mathbf{t})$  is a formula
- ▶ Disjunctions, conjunctions, negations, quantifications of formulas are also formulas

**Semantics** is inductively defined as:

- ▶  $S \models \Delta$  if  $wfm_{S|_{Open_{\Delta}}}(\Delta)$  is two-valued and equal to  $S|_{Def_{\Delta}}$
- ▶  $S \models P(\mathbf{t})$  if  $\mathbf{t}^S \in P^S$
- ▶ Usual induction for connectives

A **theory**  $T$  is a set of formulas and  $S \models T$  iff  $\forall \phi \in T, S \models \phi$

## Example: Winning positions of a game

The game:

- ▶ Two players
- ▶ Stack of  $N$  stones
- ▶ Remove 1 or 2 stones
- ▶ Last move wins

$$\forall x \text{ Pos}(x) \Leftrightarrow (x \leq N) \wedge (x \geq 0)$$

$$\left\{ \begin{array}{l} \forall x, y \text{ Move}(x, y) \leftarrow \text{Pos}(x) \wedge \text{Pos}(y) \\ \wedge (y = x - 1 \vee y = x - 2). \end{array} \right\}$$

$$\{\forall x \text{ Win}(x) \leftarrow \exists y \text{ Move}(x, y) \wedge \neg \text{Win}(y).\}$$

## Example: Winning positions of a game

The game:

- ▶ Two players
- ▶ Stack of  $N$  stones
- ▶ Remove 1 or 2 stones
- ▶ Last move wins

$$\forall x \text{ Pos}(x) \Leftrightarrow (x \leq N) \wedge (x \geq 0)$$

$$\left\{ \begin{array}{l} \forall x, y \text{ Move}(x, y) \leftarrow \text{Pos}(x) \wedge \text{Pos}(y) \\ \quad \wedge (y = x - 1 \vee y = x - 2). \end{array} \right\}$$

$$\{\forall x \text{ Win}(x) \leftarrow \exists y \text{ Move}(x, y) \wedge \neg \text{Win}(y).\}$$

## Behaviour of definitions

Two different types of updates

- ▶ Adding **rule** to definition
  - ▶ Non-monotone
  - ▶ The set of formulas that hold in all models might decrease
- ▶ Adding a **definition**
  - ▶ Monotone
  - ▶ The set of formulas that hold in all models increases
  - ▶ Same as adding a FOL-formula

ID-logic adds a restricted form of non-monotonicity, while retaining the overall monotonicity

## Usefulness

- ▶ An inductive definitions is mathematical concept
- ▶ But strongly rooted in intuition
  - ▶ Describes a constructive process, that is very natural
  - ▶ Similar to human thought process?
  - ▶ Similar to cause-effect propagations in the real world?
- ▶ ID-logic is also a useful tool for
  - ▶ Formalizing (aspects of) common sense reasoning
  - ▶ Solving computational problems

Introduction to ID-logic

ID-logic and common sense

Defaults

Ontologies

Actions

ID-logic as a computational tool

The relation to ASP and LP

Future work & Conclusion

## Defaults

### General Principle

If you define a relation, then tuples do not belong to this relation unless there is an **explicit** reason for them to do so

- ▶  $\{\forall x \text{ Flies}(x) \leftarrow \text{Bird}(x) \wedge \neg \text{Ab}(x).\}$
- ▶  $\left\{ \begin{array}{l} \text{Bird}(\text{Tweety}). \\ \text{Bird}(\text{Fred}). \end{array} \right\} \wedge \{\text{Penguin}(\text{Fred}).\}$
- ▶  $\{\forall x \text{ Ab}(x) \leftarrow \text{Penguin}(x).\}$

## Ontologies

ID-logic is a very natural fit, e.g.,

$$\left\{ \begin{array}{l} \forall x \text{ Mammal}(x) \leftarrow \text{Placental\_Mammal}(x). \\ \forall x \text{ Mammal}(x) \leftarrow \text{Marsupil}(x). \\ \forall x \text{ Mammal}(x) \leftarrow \text{Monotreme}(x). \end{array} \right\}$$
$$\left\{ \begin{array}{l} \forall x \text{ Placental\_Mammal}(x) \leftarrow \text{Primate}(x). \\ \forall x \text{ Placental\_Mammal}(x) \leftarrow \text{Rodent}(x). \\ \dots \end{array} \right\}$$

- ▶ Combine with defaults
- ▶ Multiple subdivisions

$$\left\{ \begin{array}{l} \forall x \text{ Human}(x) \leftarrow \text{Man}(x). \\ \forall x \text{ Human}(x) \leftarrow \text{Woman}(x). \end{array} \right\} \wedge \left\{ \begin{array}{l} \forall x \text{ Human}(x) \leftarrow \text{Child}(x). \\ \forall x \text{ Human}(x) \leftarrow \text{Adult}(x). \end{array} \right\}$$

## Situation calculus: Gear wheel example

**Fluents:** for all  $g$

- ▶  $Turn(g)$ : Gear wheel  $g$  is turning

**Actions:** for all  $g$

- ▶  $Start(g)$ : Start gear wheel  $g$
- ▶  $Stop(g)$ : Stop gear wheel  $g$

For every fluent  $f(\mathbf{x})$ :  $H_f(\mathbf{x}, S)$ ,  $Init_f(\mathbf{x})$ ,  $C_f(\mathbf{x}, A, S)$ ,  $C_{\neg f}(\mathbf{x}, A, S)$

$$\left\{ \begin{array}{ll} \forall g & H_{Turn}(g, S_0) \leftarrow Init_{Turn}(g). \\ \forall g, a, s & H_{Turn}(g, do(a, s)) \leftarrow H_{Turn}(g, s) \wedge \neg C_{\neg Turn}(g, a, s). \\ \forall g, a, s & H_{Turn}(g, do(a, s)) \leftarrow C_{Turn}(g, a, s). \end{array} \right\}$$

## Gear wheel example (2)

Domain specific part:

- ▶ (Direct and indirect) effects of actions

$$\left\{ \begin{array}{l} \forall g, s \quad C_{Turn}(g, Start(g), s). \\ \forall g, s \quad C_{\neg Turn}(g, Stop(g), s). \\ \forall g, s \quad C_{Turn}(g, a, s) \leftarrow \exists h \ C_{Turn}(h, a, s) \wedge Conn(h, g). \\ \forall g, s \quad C_{\neg Turn}(g, a, s) \leftarrow \exists h \ C_{\neg Turn}(h, a, s) \wedge Conn(h, g). \end{array} \right\}$$

- ▶ Particular instance:

$$\left\{ \begin{array}{l} Conn(1, 2). \\ \forall x, y \quad Conn(x, y) \leftarrow Conn(y, x). \end{array} \right\}$$

- ▶ Initial situation:  $\neg \exists g \ Initially_{Turn}(g)$

Future work & Conclusion

## Hamiltonian Path

$Ham(x, y)$  means that the edge  $(x, y)$  is in the path

$$\left\{ \begin{array}{l} \forall x \text{ Reached}(x) \leftarrow \exists y \text{ Initial}(y) \wedge Ham(y, x). \\ \forall x \text{ Reached}(x) \leftarrow \exists y \text{ Reached}(y) \wedge Ham(y, x). \end{array} \right\}$$

$$\forall x, y, z \text{ Ham}(x, y) \wedge Ham(x, z) \Rightarrow z = y$$

$$\forall x, y, z \text{ Ham}(x, y) \wedge Ham(z, y) \Rightarrow z = x$$

$$\forall x, y \text{ Ham}(x, y) \Rightarrow \text{Edge}(x, y)$$

$$\forall x \text{ Vertex}(x) \Rightarrow \text{Reached}(x)$$

- ▶ Input:  $\{ \text{Vertex}(A). \dots \text{Vertex}(S). \} \{ \text{Initial}(A). \}$   
 $\{ \text{Edge}(A, B). \dots \text{Edge}(R, S). \}$
- ▶ Find paths by generating Herbrand models

## Different approach

A Framework for Representing and Solving NP Search Problems. D. Mitchell and E. Ternovska. *Proc. AAAI 2005*.

- ▶ Use same theory
- ▶ Input: let  $R$  be a structure for  $\{Vertex/1, Edge/2, Initial/1\}$ 
  - ▶  $Domain(R) = \{A, B, \dots\}$
  - ▶  $Initial^R = \{A\}$
  - ▶  $Vertex^R = Domain(R)$
  - ▶  $Edge^R = \{(A, B), \dots\}$
- ▶ Find paths by **extending**  $R$  to model for theory
- ▶ Complexity result:  $MX(FO(ID))$  captures NP

## Implementation: MidL

### Main idea

- ▶ ID-logic extends classical logic with inductive definitions
- ▶ MidL extends SAT-solving with **incremental** WFM computation
  - ▶ Guess open atom
  - ▶ Propagate by SAT clauses
  - ▶ Propagate by definitions

### Focus

- ▶ Achieving good integration between these two components
- ▶ E.g. watched literals, clause learning,...

### Download:

<http://www.cs.kuleuven.be/~maartenm/research/midl.html>

Introduction to ID-logic

ID-logic and common sense

- Defaults

- Ontologies

- Actions

ID-logic as a computational tool

The relation to ASP and LP

Future work & Conclusion

## The relation with ASP

- ▶ Informally: very different
  - ▶ ID-logic is about representing inductive definitions
  - ▶ ASP is about representing rules governing the beliefs of a rational agent
- ▶ Formally: very similar
- ▶ Practical examples: very similar
- ▶ Straightforward transformations between large subsets of ID-logic and extended LPs
- ▶ The constructive process described by an inductive definition corresponds to reasoning process of a rational agent?

### Main difference

ID-logic has no **epistemic** component, i.e., things like *check* : *—not orphan, not  $\neg$ orphan.* are not possible

## Some correspondences

- ▶ Definitions

- ▶  $\left\{ \begin{array}{l} Reached(x) \leftarrow \exists y \text{ } Reached(y) \wedge Ham(y, x). \\ Reached(x) \leftarrow Initial(x). \end{array} \right\}$

- ▶  $reached(X) : \neg reached(Y), ham(Y, X).$

- $reached(X) : \neg initial(X).$

- $\neg reached(X) : \neg not \text{ } reached(X).$

- ▶ Open predicates (i.e., not defined anywhere)

- ▶ Nothing in ID-logic

- ▶  $ham(X, Y) \vee \neg ham(X, Y).$

- ▶ or  $ham(X, Y) : \neg not \neg ham(X, Y).$

- $\neg ham(X, Y) : \neg not \text{ } ham(X, Y).$

- ▶ Assertions

- ▶  $\forall x, y, z \text{ } Ham(x, y) \wedge Ham(x, z) \Rightarrow z = y$

- ▶  $: \neg ham(X, Y), ham(X, Z), Z <> Y.$

## Contributions of ID-logic to LP

- ▶ LPs can be used to represent **inductive definitions**
  - ▶ Well known for monotone definitions
  - ▶ WFS extends this to non-monotone definitions
- ▶ ID-logic **isolates** this informal “fragment” of LP
  - ▶ Clear, unambiguous and well-known intuitive reading
- ▶ Shows how it can be integrated into **classical logic**
  - ▶ By adding a single new primitive to the language
- ▶ Allows it to be used together with all the expertise for classical logic

### ID-logic shows

One clearcut contribution that LP has to offer to classical logic is its ability to represent inductive definitions

Introduction to ID-logic

ID-logic and common sense

Defaults

Ontologies

Actions

ID-logic as a computational tool

The relation to ASP and LP

Future work & Conclusion

## Work being done on ID-logic

- ▶ Most of the research in our group is devoted/related to ID-logic
  - ▶ Develop model generator
  - ▶ Develop a proof system (preliminary)
  - ▶ Study relation with fixpoint logics
  - ▶ Use ID-logic for data integration
- ▶ At SFU:
  - ▶ Study  $MX(FO(ID))$
  - ▶ Using ID-logic for verification
- ▶ My interests
  - ▶ Proving some modularity results
  - ▶ Relation between ID-logic and CP-logic

## Relation between inductive definitions and causality

- ▶ An **inductive definition** implicitly describes a mathematical object as the outcome of a derivation process governed by a set of rules
- ▶ A **CP-theory** implicitly describes a probability distribution as the outcome of a derivation process governed by a set of conditional probabilistic experiments
- ▶ The intuitions (and mathematics) seem very closely related
- ▶ Is an inductive definition simply a set of **deterministic causal rules** in the context of mathematical objects?
- ▶ What if we replace the “inductive definition”-primitive by a “probabilistic causal process”-primitive?

## Conclusion

- ▶ ID-logic introduces a new primitive that allows inductive definitions to be represented in a uniform and straightforward way
- ▶ Inductive definitions are important
  - ▶ In mathematics
  - ▶ For common sense reasoning
  - ▶ For solving computational problems
- ▶ ID-logic integrates this in classical logic
  - ▶ Reuse all old expertise
- ▶ Everyone who knows classical logic and who can read an inductive definition, already knows ID-logic

<http://www.cs.kuleuven.be/~maartenm/research/midl.html>
