APPENDIX No. 15.

ON THE DEDUCTION OF THE ELLIPTICITY OF THE EARTH FROM PENDULUM EXPERIMENTS.

By C. S. PEIRCE, Assistant.

Any correction to pendulum experiments whose magnitude changes progressively with the latitude needs to be very accurately determined, lest an error be thereby introduced into the resulting value of the ellipticity of the earth. The atmospheric pressure and the temperature both give rise to corrections of this class, and the coefficients of these corrections have been, in general, very inadequately determined. The experiments which have recently been published in the fifth volume of the India Survey, however, sufficiently determine these coefficients for the Kater invariable pendulums. For all other forms of pendulums which have been used, excepting the large-sized Repsold reversible pendulum, their values are quite uncertain. But by far the greater part of the valuable data at hand in reference to the relative force of gravity in different latitudes consist of the times of oscillation of Kater invariable pendulums. So that even were we able properly to correct the others for temperature and pressure they would have very little influence upon the resulting ellipticity, for their absolute number is small, and they are not usefully distributed in latitude. Subject to uncertainties of reduction as they are, the only appreciable effect of admitting them into our calculations would be to increase the apparent probable error without altering the result. Under these circumstances, it has seemed best to me in making a new calculation of the ellipticity, as derived from this class of experiments, to restrict myself exclusively to those made with the Kater invariable pendulums.* The coefficient of the effect of atmospheric pressure upon pendulums of this class was determined in 1829, by Sabine, and the later researches under the auspices of the Indian Survey have not seriously invalidated his determinations. Baily, in his report on Foster's pendulum experiments, unfeignedly took to correct all the former results for this effect, but his work is erroneous in several particulars. Thus, he applies the correction to Lütke's numbers, to which it had already been rightly applied; he omits to reduce Sabine's values to the level of the sea, and commits various other errors which cannot be so easily explained in a few words. For the coefficient of temperature effect a value has usually been assumed which was first obtained by Kater, and which is entirely incompatible with the known coefficient of the expansion of brass and with the experiments upon the periods of oscillation at different temperatures. The value adopted in the reductions of the India Survey for pendulum No. 4, which was one of Sabine's pendulums, coincides precisely with that found by Lütke; differs very little from that obtained by the Indian Survey for their other pendulum, satisfies well the experiments by Sabine at different temperatures, agrees with our general knowledge of the coefficient of expansion of brass, and has consequently been made use of by me in the reduction of all the experiments made with the Kater invariable pendulums. I have, therefore, made the necessary corrections to all the results with these pendulums, with the exception of those of the Indian series and of Lütke, which I have supposed to have been rightly reduced.

The corrections for elevation of the station above the level of the sea has hitherto been made by Dr. Young's rule, which is based on the assumption that all the earth and rock rising above the level of the sea is to be considered as attracting the pendulum as if it was so much additional matter beneath the pendulum in excess of what is found at the level of the sea. That this assumption, so foreign to the facts of the case, does not accord with the determinations of gravity made at the sea shore, and at great elevations in the neighborhood, has often been pointed out; in particular by M. Faye in the "Comptes Rendus," June 21, 1880.

Let us first consider the question *a priori*.

* The present computation was begun before Major Herschel's work was received. The principles of my procedure being different from his, I have thought it worth while to complete my work and see how far Major Herschel's and my results would agree.

The only geological cause of vast horizontal displacements of solid matter, such as alone could sensibly affect the pendulum, is denudation. This has always been at work to remove matter from the continents and deposit it on the bed of the ocean; and it seems probable that the general result of it must have been to diminish the amount of matter in those cones having their vertices at the center of the earth and their bases on our present land, and to increase the amount of matter in those cones having their bases on our present sea bed. But it would seem that the effect of such transfer is one of those of which we cannot at present take account. We must, then, regard continental elevations, as produced by the elevation of a certain thickness of matter, equivalent to a crust.

If we use the following notation:

g =gravity,

δ =density of the continent,

Δ =mean density of the earth,

r =radius of the earth,

u =length of the chord from the center to the circumference of a small circle,

h =elevation above the level of the sea,

then the vertical attraction of a cap of matter having the thickness h all over this small circle upon the point at its center is, according to Pratt,

$$\frac{3}{2} \frac{g \delta}{\Delta c} \left(u + h - \sqrt{u^2 + h^2 + \frac{uh}{c}} \right).$$

It has always been assumed that the second term of the polynomial in the parenthesis would alone be sensible except in extreme cases. If, now, we conceive that the elevation, instead of being produced by the addition of new matter, has been produced by the upheaval of the crust of thickness t , then the quantity in the parenthesis becomes

$$u + \sqrt{u^2 + (t+h)^2} - \sqrt{u^2 + t^2} - \sqrt{u^2 + h^2}$$

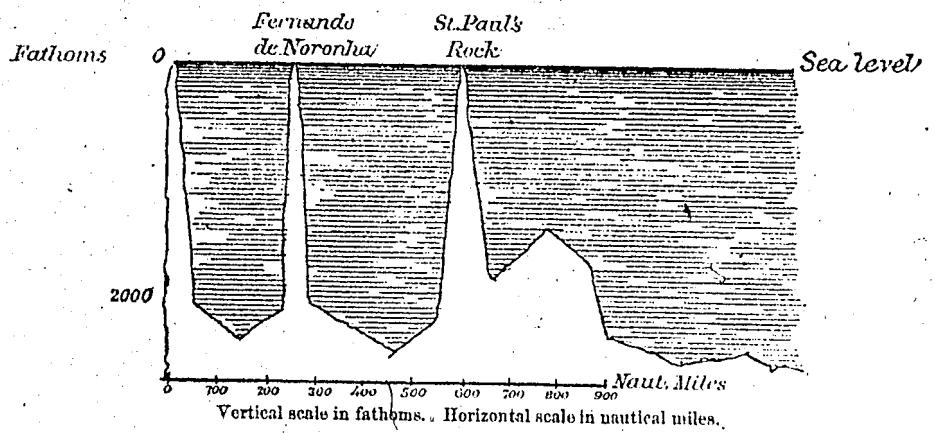

Here we perceive that that term which has generally been considered as alone sensible here disappears altogether; but a new term enters in of the first degree in h , the value of which is

$$\frac{th}{\sqrt{u^2 + t^2}}$$

It will be seen that this term, which is the principal part of the whole expression, is nearly inversely proportional to the radius of the cap, so that a large cap will have less downward attraction than a small one. The reason of this is as follows:

Through any point, p , let a line be drawn in a vertical direction; through p let a sphere be described having its center upon this line. Taking p as the origin of polar co-ordinates, let a new surface be described having the radius vector in any direction equal to that of the sphere. Then this surface will be the surface upon which a particle of matter anywhere placed will exert a constant vertical attraction upon the point p . As the center of the sphere varies its position along the vertical line through p , a succession of these inclosed surfaces of equal vertical attraction will be formed all in contact with one another at the point p . It will be seen then that the nearly spherical surface of the earth cuts all these surfaces in such a manner that the uplifting of the particles anywhere on its surface other than the immediate neighborhood of p will diminish the vertical attraction upon p . The exact calculation of the effect of the elevation of a crust being extremely troublesome, and the quantity being small, I have thought it sufficient to assume that the downward attraction would be one-tenth of the correction for elevation. This quantity which was adopted as satisfying moderately well the experiments on neighboring high and low levels is equivalent to assuming that the thickness of the crust is about one-eighth of the diameter of the space arched over; and the assumption has the same effect as if it were supposed that the continental elevations were produced by additional matter having three-fourths the density of water.

We have so far only considered the solid material of the crust. In addition to this there is the water, which simply runs down to the lowest levels; so that its whole attraction is to be considered and allowed for. Let us consider a small island lying in the midst of the sea. In the first place, if there were no water about it, the gravity would be in excess upon such an island in consequence of the depression of the sea-bed around it. This excess may, as we have seen, be roughly taken as equal to what would be produced by the downward attraction of an excess of matter sufficient to build up the island and having three-fourths the density of water. In the case of a small island the effect will be greater than this. In the case of a large island, especially one lying near a continent, the effect will be increased by the surrounding deposits of matter resulting from denudation. On the whole, then, we may roughly take the excess of gravity on the island to what it would be if the island was built up of extra matter having the density of water. Then when we take into account the attraction of the ocean itself, we may say that the excess of gravity upon an island will be about equal to what would be produced by an ocean having the general depth of the ocean bed quite outside the island and extending completely over the space occupied by the island. What is meant will be understood the moment that we look at a rough profile of the equatorial Atlantic through the islands Fernando de Noronha and Saint Paul's Island.

Coast stations are generally to be considered as really continental, since the true boundary of the continent at a depth of some 100 fathoms is considerably outside the coast. Stations near this boundary may be considered to be like deep-water islands surrounded by water of half the depth of that which is upon one side of the station. Taking the contour chart of the ocean bed given in Mr. Wild's book called *Thalassa*, I find that the following pendulum stations have to be corrected for the depth of the ocean about them:

Stations at which corrections are to be applied for attraction of water.

	Fathoms.
Hare Island	1,000
Melville Island	1,000
Galapagos	2,000
St. Thomas	3,000
Ascension	2,000
Sierra Leone	500
Bahia	1,000
Jamaica	700
Spitzbergen	500
Point Bowen	500
Valparaiso	250
Port La Coquille	3,000
Guan	3,000
Port Lloyd	2,000
St. Helena	3,000
Montevideo	200

	Fathoms.
Staten Island	500
South Shetland	500
Cape Horn	500
Fernando de Noronha	3,000
Minicoy Island	500

Rough as these corrections are, the application of them will show what we have to expect from a more exact treatment according to the principles just laid down. I have calculated the ellipticity with these corrections, and find it to be (taking $\gamma = .0052375$)

$$291.5 \pm 0.9$$

This probable error is rather smaller than that obtained by the treatment of the latest and best geodetical operations and is much smaller than that obtained hitherto from pendulum observations. Upon comparing my residuals with those of Clarke (Geodesy, p. 349), it will be observed that, as a general rule, the residuals that now remain large had previously been much larger, and are generally marine stations, from whence I infer that a more careful estimate of the attraction of the ocean would produce a still further improvement of the result. That which is most needed to improve the state of our knowledge of gravity are additional experiments in the Arctic Circle. It is desirable that these experiments should be made with the Indian apparatus, and it is also to be desired that the same apparatus should be used at Trinidad, Ascension, and Maranham, the three stations which are common to the great expeditions of Sabine and Foster.

PENDULUM EXPEDITIONS.

The results of Expeditions Nos. IX, XI, XII, XIII, XV have been reduced to VII by solving by least squares the following equations of condition:

Obs.	Calc.
VII at Greenwich — reduction of IX	= 4.9356890
VII at St. Helena — reduction of IX	= 4.9351291
VII at London — reduction of XI	= 4.9353550
VII at Greenwich — reduction of XI	= 4.9353564
VII at London — reduction of XII	= 4.9353500
VII at C. G. H. — reduction of XII	= 4.9360129
VII at London — reduction of XIII	= 4.9348326
VII at Greenwich — reduction of XIII	= 4.9348269
VII at C. G. H. — reduction of XIII	= 4.9344887
VII at St. Helena — reduction of XIII	= 4.9342726
VII at Maranham — reduction of XIII	= 4.9341242
VII at Ascension — reduction of XIII	= 4.9341940
VII at Trinidad — reduction of XIII	= 4.9341715
VII at London — reduction of XV	= 4.9350847
VII at C. G. H. — reduction of XV	= 4.9347472
VII at London	= 4.9353222
VII at Maranham	= 4.9346210
VII at Ascension	= 4.9346885
VII at Trinidad	= 4.0346596

The following are the values of the unknown quantities:

Reduction of Expedition No. IX	= - 3661
No. XI	= + 9664
No. XII	= - 284
No. XIII	= + 4926
No. XIV	= + 2371

Oscillations of VII at London	= 4.9353224
Greenwich	= 3218
C. G. H.	= 4.9349833
St. Helena	= 7642
Maranham	= 6190
Ascension	= 6877
Trinidad	= 6619

EXPEDITION NO. I.

Reduction to No. VII by London = + 4,943.

Station.	Log No. oscillations.	Red. to VII - 4.935	Mult. by 2.	Elevation corr.	Latitude corr.	Reduced.
London	4.9348281	3,224	6,448	39	13,910	2,571
Unst	50063	5,006	10,012	12	17,283	2,741
Portsoy	49512	4,455	8,910	39	16,215	2,734
