71.5.13

On the Logic of Quantity.

By C. S. Peirce.

Art. 1. All the sciences may advantageously be arranged as follows:

The first prime division consists of Mathematics, which merely frames hypotheses and traces out their consequences, and alone of all the sciences does not concern itself with <sup>positive</sup> truth. Although the mathematician is free to form any hypothesis which manifestly involves no contradiction and is only so far determinate as its determinations may affect the form of the consequences which are deducible from it, yet we find that all those general hypotheses, <sup>which (in pure mathematics)</sup> each is carried through a whole branch of mathematics, are of a few well characterized kinds. Each deals with some system of quantity; and the systems of quantity are of three <sup>entire</sup> classes, viz: 1<sup>st</sup>, the system of two values, as in the most demonstrative logic, where every proposition is either true or false; 2<sup>nd</sup>, systems of discrete quantity <sup>having more</sup> greater than two values each; 3<sup>rd</sup>, systems of continuous quantity. The <sup>problem</sup> purpose of the present paper is to ascertain why mathematics should always deal with a system of quantity, what the different possible systems of quantity are and how they are characterized, what the logical nature of mathematical infinity is, etc.

The second prime division of the sciences consists of Philosophy, which concerns itself indeed, with positive truths but only with such as would <sup>manifestly</sup> remain true whatever observation might reveal. Even

13 000002

*C. S. Peirce*

if it be denied that there is any such truth, ~~no~~ place in the scheme of the sciences must be accorded to this inquiry. For a department of science is not a body of truth but a group of possible researches after truth. But then, nobody ever maintained that philosophy was not based on observation; and it suffices to establish this ~~division~~ department of science that there are, or seem to be, some truths which are logically involved in the general fact that any observation is made, — such as, that there seems to be a world, which is not entirely homogeneous, and that there seems to be some power of observation, etc.; for these truths in seeming to be logically involved in that general fact are independent of the possible varieties of results which might be revealed by observation; and if such these truths seem to be, a branch of inquiry can be directed to them. Philosophy has two and but two branches, Logic, or the philosophy of thought, and Metaphysics, or the philosophy of being. The inquiry whether any given branch of science, such as ethics, belongs to philosophy, or to any other division of science is an application of logic. Philosophy always has <sup>reposed</sup> ~~made~~, and must <sup>repose</sup> ~~make~~, <sup>very greatly upon</sup> ~~great use of~~ mathematics; and this is particularly true of logic, which has been mathematical from the very first. Metaphysics has always been based, and must be based, upon accepted principles of logic.

The third prime division of the sciences consists of the special observational sciences. These sciences, however observationally they may be pursued, always have depended, and must depend, to an important extent upon metaphysics for their first principles. The <sup>special</sup> observational sciences are divisible

gravitation

in two ways. In the first way they are divided into the **Psychical** and the **Physical** sciences, the latter embracing the all special observational study of purely material phenomena, the former all special observational study of manifestations of mind as such, including anthropology, philology, history, etc. The physical sciences perhaps depend more upon physical principles, the psychical sciences upon physical principles.

In the second way, the <sup>special</sup> observational sciences are divided into the **Nomological**, the **Classificatory**, and the **Descriptive**. The nomological sciences study the universal laws of mind or of matter. Nomological psychics treats of the time, of the laws of association, fatigue, etc. Nomological physics treats of physical geometry, or the real properties of space, <sup>for example, viz.</sup> whether (elliptic, hyperbolic, or parabolic; also of dynamics, <sup>and molecular</sup> elasticity and thermotics, and of the phenomena. Whether the study of the properties of the ether ought to be included under Nomological or classificatory physics may be doubted. Classificatory psychics studies ~~the~~ <sup>such as language, business, worship, etc.</sup> observationally the different kinds of manifestations of mind, describes their general properties and regularities, and seeks to explain the phenomena upon the general principles of association, etc. Classificatory physics, or chemistry, describes the different kinds of matter determines their properties, and seeks to explain their constitutions on the principles of dynamics. Thus, it treats of the crystalline forms of the different substances; <sup>and in</sup> in regard to <sup>one</sup> the great class of substances, the protoplasm it has to describe <sup>and explain</sup> the organized forms into which they grow, thus <sup>developing</sup> producing the science of biology. **Descriptive** The Descriptive <sup>has</sup> sciences describe individual objects and seek to explain <sup>their origin and progress</sup> them upon the principles of nomological and classificatory science. Under descriptive psychics we place <sup>(political geography, laws,</sup> history of all kinds, theology, etc. Under descriptive physics

*W. F. Floyd*

we have astronomy, geography, geology, etc.

The fourth prime division of science consists of the Arts. Every art depends, at once, upon psychical and upon physical knowledge. Some arts are almost entirely psychical, such as rhetoric, ethics, religion (the art of propitiating the highest power), jurisprudence, etc.; others are almost entirely physical, such as glass-blowing, horology, and hundreds of others; while many arts require high knowledge of both kinds, such as painting, music, etc. But this classification of the arts is most complicated.

I propose, in a series of papers, to examine the logic of each of the above twelve branches of science.

Art. 2. We remark in the world three categories of elements. The first comprises the qualities, such as red, bitter, tedious, hard, heart-rending, agreeable, and countless manifold varieties which are utterly unknown to us. They are potentialities and general in their nature, <sup>but there is no reason why any of them should be as such.</sup> The second category comprises actual occurrences. They are individual <sup>and</sup> brutally insistent. The third category comprises laws. No fact nor collection of facts can constitute a law which goes beyond any completed facts to determine how facts that may be shall be characterized. In these, the ideal world of qualities and the actual world of facts overlap.

Qualities are self-contained. The fact that a thing is green, so long as the green is looked upon as a mere quality, does not logically involve anything else being the subject of any other quality. Actuality is double in its nature. In the act of will, which is its type, there is the acting subject and the reacting object. The happening of an event consists in the previous existence of one state of things, and the subsequent existence of

power  
should

another. To think of anything as having individual existence involves to us every case two a pair of factors. Law has a triple nature. It supposes, in the first place, a subject which it affects. Then, there must be a cause. That is, that affected subject must furnish the condition of the law; and this it can only do by a relation to something else. Then the effect of the law is realized in another relation to a third thing. There are other ways in which this element of the world may be conceived; but in every case, three things are involved.

The result of this universal phenomenon is that the conceptions of First, Second, and Third present themselves in Logic at every turn. It is well to reflect upon the true nature of these conceptions. The One that we hear of so much in philosophy is a synthetic unity, that is, a totality, or something connected with a collection. That is as far as possible from the pure idea of the First. The First is that which springs out of nothing, the prominent element in the conception of spontaneity. It is so utterly free from all trammels that it does not even think involve the conception of a second. It stands on its own feet and is what it is, — red is red and green is green, — without reference to anything else. The Second, on the contrary, is so only by virtue of another thing which is its second. The pair react. But they do so brutally, without a reason; for a reason would be a mediating third. Tertium in Latin is nearly synonymous with Medium. That is the conception of the category. It is the continuous ever mediating line which leads from one extremity to the other. The ideas are, then, <sup>Firstness, Otherness,</sup> ~~Firstness~~, Mediation; or the Idea, the Fact; and the Evolution.

Soberly treatise of Terms, Propositions, and Inferences. <sup>of terms may be appears in</sup> ~~Taking the second of these~~  
~~different lights in different ways of developing logic; but the most convenient~~  
~~as well as the most philosophical way is to regard the term as a verb.~~

106 6  
Art. 3. Any world, or product of experience, may be studied in three ways, according as the mind gives prominence to its firstness, to its secondness, or to its thirdness.

It may, in the first place, be scrutinized <sup>in</sup> with respect to its qualities, regardless of anything more than <sup>how</sup> what each object appears. That is the way in which the Artist, who relatively to other non-artists is always an impressionist, looks upon an experiential presentment. His conversation shows how he values each object for itself, how he delights in the exceptional and in the original, and how he distrusts, and even dislikes, mental arrangements in sets that are not to be seen in nature.

The world may, in the second place, be examined with reference to the actions and reactions of different objects upon one another. This is the way the Practical Man studies the world. How that man's mind runs upon pairs will be manifest as soon as he talks. His divisions are almost all dichotomies: every transaction is either honest or dishonest; those he deals with are either friends or enemies; doctrines are either commendable or reprehensible.

Finally the world may be studied in order to discover how things are brought about, what the laws of the phenomena are, what idea governs the cosmos. This is the way in which the Philosopher, or man of intellect, is interested in the world. He loves to group objects in threes, and the nature of his pursuit leads him often to do so without remarking it.

Def. 4. Singular facts, - facts about single subjects, - are of only one type, but what this means must be gathered from comparison with dual and with plural facts.

Dual facts, - facts about pairs of subjects, - are of two types, first, those which imply no more about their subjects than that they have certain qualities between which some comparison is made; and second, those which imply more about their subjects than is true of them in their separate existences, something <sup>real and positive</sup> which could not be true of one if the other did not exist to enable it to be true, in other words a real action and reaction between the individuals. This is the old distinction between real relations and relations of reason. Real relations exhibit the fully developed type of duality. In this case, it is what happens to the individuals, <sup>the actions of them,</sup> which pairs them. Relations of reason imply no other facts than the possession of two qualities severally by two individuals; and it is primarily the qualities that are paired. One individual can only act upon a different individual; the individual things must be two. One part of a thing may act upon another part, or the individual as <sup>it</sup> he is at one instant upon the individual as he is at another instant. But these are different individuals; for an individual is strictly that which is here and now, - a particle at a given instant. But relations of reason, such as identity, likeness, etc. may subsist between an individual taken as first of the pair and the very same individual taken as second of the pair.

Plural facts, — facts about sets of objects greater than pairs, — are of three types, first, those which imply no more about their subjects as they exist than that they severally possess certain qualities between which comparison is made; secondly, those which imply no more about their subjects than that actions take place between the different pairs of them; and thirdly, those which imply more about their subjects than <sup>can be</sup> true of them as separate units or as pairs, something real and positive concerning each which could not be true of it were not two others there to enable it to be true. For example, if the color of A is intermediate between the color of B and the color of C, this is a triple fact about A, B, and C; but all that is true of these objects is that they have severally certain colors, one or two of the objects might be imaginary and only one existent, and still the <sup>triple</sup> fact would remain true of that one. Next suppose the waters of two streams to join. Then of the three stretches of river, two above and one below the junction, only two pairs <sup>real</sup> act upon one another. The two above actually join, which would be impossible unless both were existent; and each of these above flows into the one below. These three actions constitute the whole fact; but the fact that A and B join to form C is a triple fact. Finally, suppose two men to agree that a certain river shall be dammed. This is something done; it <sup>does</sup> not consist in the possession of three independent qualities by the two men and by the river. But though it is something done, it does not consist of three actions between pairs of objects. The two men agree, <sup>result</sup> that they cannot do without agreeing upon something to be brought about. So what happens to the river is that it is made the subject

of a bargain; and it takes two persons to make a bargain.

Art. 5. It thus appears that qualities, or some <sup>genus</sup> class of elements of which qualities form a species, are requisite for the existence of singular facts; that individual ~~or~~ material things, or some genus of which these form a species, are requisite for the existence of real dual facts; and that thoughts, or some genus of which these form a species, are requisite for the existence of real plural facts. >

Note In order to ascertain what the limits of those genera are, it will be necessary to consider just how those different <sup>categories</sup> sorts of objects become requisite for to those kinds of facts.

The ~~Babylonian~~ Chaldean metaphysicians were quite right in holding that if the world has come about as the result of any process, there must have been, in the beginning, — or immediately after absolute nothingness, — a state of Chaos in which the <sup>real</sup> state of things corresponded to our state of mind when we only ask questions but assert nothing. Nothing, then, existed; for existence supposed some determinacy. From this Chaos the first thing <sup>that arose</sup> made must have been a partial determination. Now a partial determination precisely defines a quality, in the sense in which a quality is the requisite of a singular fact. That, then, must have been the first <sup>product of</sup> step in the evolution.

It is interesting, and not wholly without importance to note that those primitive thinkers without ~~any~~ bias from previous metaphysical systems, made the work of the first day of creation to be light, by which, no doubt, they meant appearance, — but appearance in existence, not to vision; — and appearance and other sensible phenomena, abstracted from the

faculty of sensation, causes nothing but partial determination and generic.  
 The Chaldeans also dimly ~~perceived~~ <sup>conceived</sup> that the next step must have been toward  
 duality, for they declare that on the second day the world was <sup>segmented</sup> separated into  
 two parts. Whether or not it was the step that came next, it is the one most conveniently considered next.

As long as nothing existed but partial determinations, there could be no  
<sup>incompossible</sup> ~~real~~ duality. For <sup>elementary or indecomposable</sup> real duality supposes something to be true of a thing  
 which is not true of it in itself. Now nothing is true of a partial deter-  
 mination but the <sup>determinations that go to make up</sup> elements of that determination. ~~At least~~ <sup>Suppose</sup> anything  
<sup>further</sup> ~~is~~ true, and you simply have a further determination, <sup>a new thing, not the</sup> ~~same~~ as  
<sup>with something more true of it.</sup> ~~different~~ thing. In order, then, to <sup>elementary</sup> make true duality possible, it  
 was necessary that something should exist which could have different  
 determinations <sup>while</sup> ~~and~~ <sup>retaining</sup> yet retain its identity. That is, there must be something  
 possessing <sup>self-</sup> identity and otherness from all else, ~~not~~ independent of  
 what its determinations may be. Now that which preserves identity and  
 otherness from all else, whatever partial determinations <sup>it may receive, is</sup>  
 as good a definition of matter as ever was made. <sup>posed. Yet it is not only a partial determination. For</sup> But it is further requisite  
 that something should be <sup>really (yet not essentially but)</sup> accidentally true of matter A and by virtue of  
 matter B, this something being such as could not be true of <sup>identical</sup> matter in  
 itself. This while ~~but~~ <sup>in</sup> ipso facto something becomes really and acci-  
 dentally true of matter B by virtue of matter A, which could not be true  
 of any identical matter in itself. <sup>Whatever</sup> What is true of matter A is necessarily <sup>of the</sup>  
<sup>nature of</sup> partial determination; and what is true of matter B is necessarily <sup>a partial determination</sup> a partial  
 determination. But that is not all; for <sup>what is true of A is</sup> what is true of A <sup>could be true of</sup>  
 A or B, <sup>yet</sup> in itself. It must, therefore, be something of that nature, <sup>but</sup> different from

Cold thing

h of 62

owing to  
 that by duality, it must be that ~~what~~ what is true of A is a junction of two  
 partial determinations (not a mere sum, for that would make one partial  
 determination) which remains two; and the same with B. And further these  
 two junctions must be joined, and mutually produce each other. All that is  
 logically necessary from the essence of duality. It describes the action  
 of material substance on another, - as for example in impact. There is a  
 change of quality in each of the pair and these two changes are brought  
 together. Thus we see how and in what sense it is that <sup>elementary</sup> duality requires matter

x centre

and further requires that material substances should be capable of acting  
 upon each other in pairs.

~~Material substances are incapable of elementary triplicity~~

Pure

~~There~~ <sup>There</sup> matter is incapable of producing elementary triplicity, so long as all its  
 action is by pairs. For elementary triplicity supposes something to be <sup>really</sup> true of  
 A which <sup>could neither be</sup> is not and cannot be true of anything essentially <sup>ie. from the</sup> of its own nature  
<sup>the subject itself</sup> that substance nor yet by the <sup>action</sup> of anything upon it, but by virtue of <sup>its</sup> ~~the~~  
~~ipse facto~~ <sup>it,</sup> in its junction with, the ~~mutual~~ fact that B and C, two <sup>subjects</sup> inde-  
 pendent ~~subjects~~ <sup>are some</sup> ~~related~~ have some relation to each other. Now,  
 were A matter, ~~that~~ <sup>and the</sup> fact that B <sup>was related to</sup> with C acted upon A, that relation would be ipse  
facto make a material substance. For example if the mutual gravitation of two bodies B and C  
<sup>was found to produce</sup> produced any effect upon an intervening body, A, independent of the several actions  
 of B and C severally upon A, every physicist would take that as a perfect  
 demonstration that gravitation was action at a distance but that there was  
 a medium, for <sup>if</sup> ~~now~~ there is action upon A, there is ipse facto matter; for <sup>the</sup> smaller  
 subject of action is by definition matter. But if there is any such intervening matter

*Walter*

explains the action between A and the relation of B to C, there is no ineliminable  
 triplicity. For in that case, calling the intervening subject D, the fact is nothing  
 more than this, that B acts upon C by acting upon D, which in turn acts  
 upon C, and D, when so affected, acts upon A. In order, then, that elemental  
 triplicity should be possible, A must be something upon which no material  
 thing can exert any action but of concerning which the fact, - or true proposition -  
 that two independent things <sup>B and C</sup> react upon one another, should, <sup>given</sup> fact, render  
 something true. But even so that fact becomes the subject of a <sup>dual</sup> relation with A,  
 between and the triple relation merely consists in this <sup>dual</sup> relation of A <sup>between</sup> to this  
<sup>fact or proposition</sup> with the dual relation between B and C. The only way of in-  
<sup>which</sup> preventing this decomposibility can be avoided is by A having such an  
 action upon the relation between B and C that to be so related to any  
 relation implies that the subject is so related to its relation to that  
 relation. In that case, there is no ultimate relation by means of which the  
 triplicity can be decomposed into dualities. Thus, elemental triplicity  
 requires a subject of such a kind that it is capable of such a relation  
 to a fact <sup>concerning</sup> between independent subjects that whatever is so related to  
 a relation is so related to its own relation to that relation. <sup>We know</sup>  
<sup>do something deliberately, or as we may say to</sup> <sup>mean</sup> <sup>to do something</sup>  
 no subjects of this kind except thought or reason. <sup>is</sup> <sup>intend</sup> <sup>to intend</sup> <sup>to do it</sup>, and <sup>is</sup> <sup>mean</sup> <sup>to mean</sup> <sup>to mean</sup> <sup>to do it</sup>, and so  
 on ad infinitum. To know and to know that we know, are says <sup>the same thing</sup>,  
<sup>rights</sup> If he means that to imply is to imply that we imply, he is  
 cannot be accomplished, while yet none of these actions can take place until the

13 000013

[ ] = crossed out by A in res

next preceding it has made that relation which is to serve the succeeding one for a subject, it is necessary that A should hold the whole series within itself, in the sense that the whole series cannot but exist as soon as A exists, or exists such as it has to be the subject of the triplicity. <sup>This is to say that A is</sup> A is therefore made by the relation between B and C. Yet it is also to say that ~~the~~ the whole series of relations are but adjuncts to A's existence. But B and C are independent of A. Therefore, it is not B and C as they are within themselves or for each other which is adjunct to A; but there must be somethings which stand for B and C and replace them for A, which are adjuncts of and dependent upon A.

Art. 3. Logic discriminates between true and false propositions. That is the final end of logic; and this is the reason why a philosophical development of logic must begin with the proposition, not the term. From a mathematical point of view, we may say that being true and being false are the two values one of which every proposition has. In probable logic there is a continuous line of values from certain truth to certain falsity. In the logic of continua, a proposition may be true, or the truth may lie at the limit of what the proposition admits, or the proposition may be quite away from the truth. But in the syllogistic logic with which we are alone concerned at the outset, the system of logical values has but two grades and is thus the most rudimentary of all systems of quantity.

A term may conform to the reality or not; that is, it may signify ~~some~~ a kind of which there are examples in the universe of discourse or it may not. It is therefore not accurate to define a proposition as that which is either true or false. But a proposition should be defined as <sup>that</sup> which professes to be true, or assigns a logical value to itself. <sup>The truth</sup> Whether is defined as that logical value which a proposition assigns to itself. <sup>Whether</sup> or not there really is such value, <sup>whether there is any truth is</sup> ~~is another~~ a question, not of definitions, but of fact.

The first postulate of the mathematics of logic is that every proposition really has a logical value; namely, there are propositions, called facts, which really have the value that every proposition assigns to itself. Calling ~~any~~ <sup>any</sup> fact,  $x$ ,  $x$  has the value it says it has, that is  $x$  is  $x$ . This is the principle of identity.

log Q

that there is a... logical value, that

The second postulate of the mathematics of logic is that there are more logical values than one. There is falsity as well as truth; and falsity differs from truth in this sense, that the same proposition cannot have both ~~both~~ these logical values. This is the principle of contradiction.

Let  $x$  be any algebraical expression of a proposition. Then, a heavy dash, called an obelus, drawn over  $x$ , has, in the general algebra of logic, the effect of negating  $x$ , that is, of converting the whole into some proposition, - if there be any such proposition, - called a negative of  $x$ , which asserts something which necessarily renders its logical value different

from that of  $x$ , and asserts nothing more. The second postulate may assert, then, that every proposition has a negative; that is there is some proposition ~~which has a logical value other than that of the first proposition.~~ <sup>which has a logical value other than that of the first proposition.</sup> ~~that every has a negative.~~ <sup>that every has a negative.</sup> The negative being other than <sup>the first proposition,</sup> the latter

is other than this negative. The postulate is, then, that any proposition  $x$ , is a negative of a negative of itself, that is, has a logical value other than some logical value other than its own. That is,

(1)  ~~$x$  is  $\bar{\bar{x}}$ .~~ If  $x$  is true, ~~so~~  $\bar{\bar{x}}$  is true.

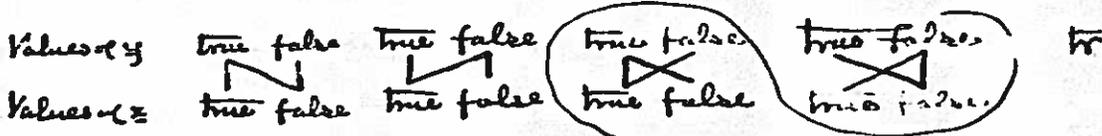

~~The third~~ This would be true even of the system of values of propositional logic <sup>and</sup> or of that of the logic of continuity.

The third postulate of the mathematics of logic is, that there is no third logical value, so that every proposition is either true or false. This is the principle of excluded middle (principium exclusi tertii). That is, if a proposition has a <sup>logical</sup> value other than <sup>a given proposition</sup> the value other than <sup>none</sup> its own (neither of which values does this postulate assert to be possible) then the former proposition must have the logical value of the latter. Further, if B asserts no

$Y = X$ . If a proposition,  $N$ , asserts so much as is necessary & renders its value the latter function of the value of a proposition,  $M$ , and asserts no more,  $N$  is, as we have seen, the negative of  $M$ ;  $N = \bar{M}$ .

The other functions of single variables are exhibited in the following diagrams.

In the first diagram  $y$  has that mode of dependence upon  $x$  that a consequent has upon its antecedent; that is, if  $x$  is true  $y$  is true, but if  $x$  is not true,  $y$  may or may not be true. The second diagram shows the converse relation, the third the negative of the first, and the fourth the negative of the converse relation.

There is thus but one fundamental function here among the four.

In this <sup>general</sup> algebra <sup>of logic</sup> ~~the~~ sign  $\llcorner$ , is called the copula of inclusion, is used to denote mean that the proposition written after it is consequent upon the proposition written before it as antecedent, in the sense that their logical values are connected as shown in the diagram.

The relation of antecedent to consequent, in this sense, may be defined in terms of <sup>the same</sup> ~~these~~ ideas <sup>of Article 33 as follows:</sup> ~~also that have been already here~~ Namely, this relation is to say that  ~~$x \llcorner y$~~

First,  $x \llcorner y$  implies that <sup>the proposition</sup>  $x$  virtually assigns to the proposition  $y$  the same logical value, that it assigns to itself;

Secondly,  $x \llcorner y$  implies nothing not which does not necessarily follow from the first clause of this definition, <sup>part</sup>

In connection with this definition <sup>three</sup> ~~two~~ more postulates of the mathematics of logic present themselves.

The fourth postulate is that if the logical value which a proposition assigns to itself is correct, then, <sup>ipso facto,</sup> the logical value which it <sup>virtually</sup> assigns to any other proposition is correct. This may be stated thus: if A <sup>virtually</sup> assigns its <sup>logical</sup> own value to B, then it <sup>virtually</sup> assigns that value to every proposition, to which B <sup>virtually</sup> assigns its own value. Or,

(3) If  $x < y$  and  $y < z$ , then  $x < z$ .

<sup>The name of this principle is</sup> This is called the Nota notae (that is, ~~Not~~ from the first words of the formula "Nota notae is nota rei ipsius".) It is also called the principle of the transiiveness of the copula. It is ~~essentially~~ <sup>essentially</sup> substantially the same as "Dictum de omni", and it has borne several other designations in logic.

The fifth postulate is that if all the <sup>logical</sup> values which a proposition <sup>virtually</sup> assigns to other propositions are <sup>in fact</sup> correct, <sup>that makes</sup> then the value which it assigns to itself <sup>is</sup> correct. ~~Or, if~~ This may be stated thus: if <sup>the</sup> proposition A <sup>virtually</sup> assigns its own value to every proposition to which the proposition B <sup>virtually</sup> assigns its own value, then A <sup>virtually</sup> assigns its own value to B. Or

(4) If for every proposition,  $x$ , such that  $y < x$ , it is ~~not~~ that  $x < z$ , then  $x < y$ .

<sup>By other words, of which it is</sup> ~~if~~ everything which a predicate means is true, that predicate is true. This is the <sup>Principle of reasoning from definition to definition.</sup> ~~Principle of reasoning from definition to definition.~~ <sup>It also governs the Second Aristotelian figure of syllogism.</sup>

In the domain of provable logic, it becomes very important as the principle of hypothetic syllogism, or inference from consequent to antecedent.

The sixth postulate is that if none of the propositions which <sup>virtually</sup> assign their values to a given proposition assign correct values, then that proposition ~~does not have~~ <sup>has</sup> a correct value to itself. ~~that if all the propositions are virtually refused to a proposition~~ <sup>values which</sup> ~~propositions are virtually refused to themselves~~ <sup>are</sup> ~~then the value~~ <sup>assigned</sup> ~~assigning them same values to~~ <sup>themselves</sup> are correctly assigned, then the value

Let  $x$  be any algebraical expression of a proposition. Then, a heavy dash, called an obelus, drawn over  $x$ , has the effect of negating it, that is of converting it into a proposition which essentially, that is, in its meaning, asserts what is necessary to make its <sup>logical</sup> value different from that of  $x$  and asserts nothing more. Taking  $=$  as the sign of logical equality, <sup>truth, of</sup> or essential sameness of value, and  $\neq$  as the sign of essential otherness, or secondness, of logical value, we have.

(1)

$$\bar{x} \neq x$$

(2)  $\bar{x}$  asserts nothing which is not <sup>logically necessitated</sup> ~~implied in (1)~~ by (1).

The third postulate of the mathematics of Logic is, that there is no third logical value, so that every proposition has the value either of  $x$  or of  $\bar{x}$ , - is either true or false. This is the principle of excluded middle, often call (Principium exclusi tertii.) As Boole remarked, it is as much as to say that every proposition satisfies one <sup>fixed</sup> ~~fixed~~ quadratic equation. For if two numbers  $t$  and  $f$ , represented the true and the false, we might in ordinary algebra write  $(t-x)(x-f) = 0$ . If, as Boole did, we borrow from <sup>the calculus</sup> probabilities the expression of truth by 1 and of falsity by 0, we get Boole's expression for the fundamental quadratic  $x(1-x) = 0$ . But in the general algebra of logic here described, we can express this postulate thus:

(3)

$$\bar{\bar{x}} \text{ is } x.$$

That is, if a proposition were to have a value other than a value other than a value of  $x$  (and <sup>though</sup> this postulate does not assert that any such values are possible) then it must have the value of  $x$ ; and not asserting anything that it does not need to assert to conform to that condition, it must assert  $x$ .
